## Integration of AquaCrop Modelling & Numerical Weather Predictions

## RESULTS

## AQUACROP EXERCISE AND INTEGRATION WITH NWP

Task of students of modelling was to create input files and run the model for obtaining yield and water productivity of winter wheat in Novi Sad.

Task of students of NWP was to create a short time period (8 days) of weather data including average temperature, relative humidity, wind speed, sola radiation and precipitation for Novi Sad location

Further, the two groups integrated their activities as the predicted weather was used into AquaCrop and results were compared with a second simulation where the model was fed with real weather data for the same period.

The aim of the integrated exercise was to assess the impact of predicted weather data on the crop simulation

# Conclusion

- The two run with AquaCrop led to a very similar final result in terms of water productivity, biomass and yield of tomato grown in 2016 in Novi Sad.
- Looking at crop transpiration, water productivity and biomass accumulated during the 8 days for which weather data were compared (observed vs NWP) we observe that a even a small difference (rainfall and temperature, especially) in data led to a difference in the simulated processes
- We can conclude that as AquaCrop is essentially a soil water balance model, it is very sensitive to weather data and longer period of time should be tested to assess the impact of NWP data on the final simulation
